problem description

Given a set *P* of points in Euclidean plane, find a tour of minimum cost that visits all the points of *P*.

- known to be NP-hard
- objective of this talk: algo (PTAS) to compute an *approximate tour* whose *expected length* is $(1 + \epsilon)\tau_{OPT}$ in $O(n(\frac{\lg n}{\epsilon})^{O(\frac{1}{\epsilon})})$ time

for the convenience, we let the following:

$$1 > \epsilon > \frac{1}{n}$$

P is contained in $[\frac{1}{2}, \frac{1}{2}] \times [1, 1]$
diam(*P*) $\ge \frac{1}{4}$

(Arora's PTAS for the Euclidean TSP)

Outline

1 algorithm

2 analysis

(Arora's PTAS for the Euclidean TSP)

round the input points to grid points

• set up a grid with sidelength $G = \{\frac{1}{n \lceil \frac{32}{\epsilon} \rceil}(i,j) | i, j \text{ are integers} \}$

round the input points to grid points

- set up a grid with sidelength $G = \{\frac{1}{n \lfloor \frac{32}{\epsilon} \rfloor}(i,j) | i,j \text{ are integers} \}$
- round (snap) each point in *P* to an arbitrary corner (grid point) of the grid cell in which it is located \rightarrow the resultant point set is *Q*
 - this would guarantee the quadtree to be constructed for Q to have logarithmic depth

• consider the unit square with its southwest corner at $(\frac{1}{2}, \frac{1}{2})^2$ as the square of the root node

²later, this corner will be fixed at a point randomly chosen from the square with the southwest and northeast corners respectively at (0,0) and $(\frac{1}{2}, \frac{1}{2}) \square \lor \triangleleft \square \lor \triangleleft \equiv \lor \triangleleft \equiv \lor \triangleleft \equiv \lor \triangleleft \supseteq$ (Arora's PTAS for the Euclidean TSP) 5/25

- consider the unit square with its southwest corner at $(\frac{1}{2}, \frac{1}{2})^2$ as the square of the root node
- since the minimal distance between a pair of points of Q is at least $\frac{1}{n \lceil \frac{32}{\epsilon} \rceil}$, it suffices to have the leafnode square sidelength $\frac{1}{n \lceil \frac{32}{\epsilon} \rceil}$

- consider the unit square with its southwest corner at $(\frac{1}{2}, \frac{1}{2})^2$ as the square of the root node
- since the minimal distance between a pair of points of Q is at least $\frac{1}{n \lceil \frac{32}{\epsilon} \rceil}$, it suffices to have the leafnode square sidelength $\frac{1}{n \lceil \frac{32}{\epsilon} \rceil}$
- height *H* of the quadtree is $O(\lg n)$

level of root is 0; for every $0 \le i \le H$, grid corresponding to level *i* is denoted with G^i and the length of any edge of G^i is $\frac{1}{2^i}$

- consider the unit square with its southwest corner at $(\frac{1}{2}, \frac{1}{2})^2$ as the square of the root node
- since the minimal distance between a pair of points of Q is at least $\frac{1}{n \lceil \frac{32}{\epsilon} \rceil}$, it suffices to have the leafnode square sidelength $\frac{1}{n \lceil \frac{32}{\epsilon} \rceil}$
- height *H* of the quadtree is $O(\lg n)$

level of root is 0; for every $0 \le i \le H$, grid corresponding to level *i* is denoted with G^i and the length of any edge of G^i is $\frac{1}{2^i}$

portals along the quadtree square sides

introduce equi-spaced $m = \frac{20H}{\epsilon}$ (which is $O(\frac{\lg n}{\epsilon})$) *portals* along each side of each quadtree square together with four at the corners of the same ³

³ choosing m + 1 as a power of two, each portal on the sides of a level i - 1 square are at the same location as a portal on the side of some level i square contained in the level i = 1 square a > 0 (Arora's PTAS for the Euclidean TSP) 6/25

requisite characteristics of a constrained tour

• tour is permitted to cross an edge *e* of a quadree square only via portals on *e*

(Arora's PTAS for the Euclidean TSP)

イロト イボト イヨト イヨト

requisite characteristics of a constrained tour (cont)

• no portal can be used more than twice

requisite characteristics of a constrained tour (cont)

- no portal can be used more than twice
- tour can use at most $r = \frac{90}{\epsilon}$ i.e., $O(\frac{1}{\epsilon})$ portals corresponding to any side of any quadtree square i.e., tour need to be *r*-light w.r.t. any quadtree square edge

requisite characteristics of a constrained tour (cont)

- no portal can be used more than twice
- tour can use at most $r = \frac{90}{\epsilon}$ i.e., $O(\frac{1}{\epsilon})$ portals corresponding to any side of any quadtree square i.e., tour need to be *r*-light w.r.t. any quadtree square edge

is it possible to have such a tour while being a good apprx to an optimal tour?

イロト イポト イヨト イヨト

nested parenthesis structure of portal-to-portal paths

• portal-to-portal paths follow parentization; hence, one can try all settings of parenthesis, translate these into possible layouts of paths and discard the ones that have intersecting paths

nested parenthesis structure of portal-to-portal paths

- portal-to-portal paths follow parentization; hence, one can try all settings of parenthesis, translate these into possible layouts of paths and discard the ones that have intersecting paths
- therefore, the number of layouts of k portal-portal paths in grid square is the k^{th} Catalan number, which is $\frac{1}{k+1}\binom{2k}{k} = O(2^{2k})$

(Arora's PTAS for the Euclidean TSP)

valid solutions of any grid square

• for every 0 to 4*r* portal combination of 4m + 4 portals on the boundary, considering that each chosen portal can be used 1 to 2 times, for every permutation *p* of the chosen portals, alternately mark portals in *p* with enter-exit \rightarrow number of subproblems $\leq \sum_{i=0}^{8r} {\binom{2(4m+4)}{i}}i!$ i.e., $(\frac{1}{\epsilon} \lg n)^{O(\frac{1}{\epsilon})})$

 $^{^4}$ a collection of subpaths (which intersect this square) of the apprx tour being constructed $_3 < _{\odot}$ (Arora's PTAS for the Euclidean TSP) 10/25

valid solutions of any grid square

- for every 0 to 4*r* portal combination of 4m + 4 portals on the boundary, considering that each chosen portal can be used 1 to 2 times, for every permutation *p* of the chosen portals, alternately mark portals in *p* with enter-exit \rightarrow number of subproblems $\leq \sum_{i=0}^{8r} {\binom{2(4m+4)}{i}}i!$ i.e., $(\frac{1}{\epsilon} \lg n)^{O(\frac{1}{\epsilon})})$
- find a minimum cost feasible subtour⁴
 - feasibility criteria: precisely satisfies the portal marking of that quadtree square; non-intersecting; subtours cover points belonging to quadtree square

 $^{^4}$ a collection of subpaths (which intersect this square) of the apprx tour being constructed $_3 < _{\odot}$ (Arora's PTAS for the Euclidean TSP) 10/25

valid solutions of any grid square

- for every 0 to 4*r* portal combination of 4m + 4 portals on the boundary, considering that each chosen portal can be used 1 to 2 times, for every permutation *p* of the chosen portals, alternately mark portals in *p* with enter-exit \rightarrow number of subproblems $\leq \sum_{i=0}^{8r} {\binom{2(4m+4)}{i}}i!$ i.e., $(\frac{1}{\epsilon} \lg n)^{O(\frac{1}{\epsilon})})$
- find a minimum cost feasible subtour⁴
 - feasibility criteria: precisely satisfies the portal marking of that quadtree square; non-intersecting; subtours cover points belonging to quadtree square

— to achieve efficiency, build the subtours in bottom-to-top fashion: using memoization of DP, from leaf nodes to root of the quadtree

 $^{^4}$ a collection of subpaths (which intersect this square) of the apprx tour being constructed $_3 < _{\odot}$ (Arora's PTAS for the Euclidean TSP) 10/25

dynamic programming over squares of quadtree grid

• interaction between problems is according to the organization of quadtree nodes

dynamic programming over squares of quadtree grid

- interaction between problems is according to the organization of quadtree nodes
- memoize the subproblem solutions

dynamic programming over squares of quadtree grid

- interaction between problems is according to the organization of quadtree nodes
- memoize the subproblem solutions
- base case: if a square has $O(\frac{1}{\epsilon})$ points of Q, then solve that subprobelm by brute force

DP: assemble subtours from children

• at every non-leaf node, for every chosen portal permutation, save these entries in the DP table: portal permutations of each child node which together caused the minimum cost subtour at the parent

(Arora's PTAS for the Euclidean TSP)

time complexity

• number of subproblems to pursue at each quadtree node $\leq \sum_{i=0}^{8r} {\binom{2(4m+4)}{i}i!}$ i.e., $(\frac{1}{\epsilon} \lg n)^{O(\frac{1}{\epsilon})}$

time complexity

- number of subproblems to pursue at each quadtree node $\leq \sum_{i=0}^{8r} {\binom{2(4m+4)}{i}i!}$ i.e., $(\frac{1}{\epsilon} \lg n)^{O(\frac{1}{\epsilon})}$
- subproblem at each quadtree node (ignoring the recursive subproblems) can be solved in $\left(\left(\frac{1}{\epsilon} \lg n\right)^{O(\frac{1}{\epsilon})}\right)^{O(1)}$ time
 - assembling: each subproblem solution of 1^{st} child with each . . . with each subproblem solution of 4^{th} child
 - and, checking whether the assembled subtour is according to enter-exit constraints and non-intersecting within the quadtree square

time complexity

- number of subproblems to pursue at each quadtree node $\leq \sum_{i=0}^{8r} {\binom{2(4m+4)}{i}i!}$ i.e., $(\frac{1}{\epsilon} \lg n)^{O(\frac{1}{\epsilon})}$
- subproblem at each quadtree node (ignoring the recursive subproblems) can be solved in $\left(\left(\frac{1}{\epsilon} \lg n\right)^{O(\frac{1}{\epsilon})}\right)^{O(1)}$ time
 - assembling: each subproblem solution of 1^{st} child with each . . . with each subproblem solution of 4^{th} child
 - and, checking whether the assembled subtour is according to enter-exit constraints and non-intersecting within the quadtree square
- since there are $O(n \lg n)$ nodes in the quadtree, the time is $n(\frac{1}{\epsilon} \lg n)^{O(\frac{1}{\epsilon})}$ (including the time to brute-force enumeration at leaf nodes)

error type (i): rounding points in *P* to get to *Q*

• The error in making π_{opt}^Q to touch points of *P* is

$$\leq n(2\frac{\sqrt{2}}{n\lceil\frac{32}{\epsilon}\rceil})$$

$$\leq \frac{4\epsilon}{32}$$

$$\leq \frac{\epsilon}{2}OPT \quad (\text{since } OPT \geq diam(P) \text{ which is } \frac{1}{4})$$

find an Eulerian tour in the graph

patching lemma: patch the path with respect to a line segment $q_1 \\ q_2 \\ p_2 \\ p_2 \\ p_2 \\ p_2 \\ q_3 \\ q_4 \\ q_5 \\ q_$

find an Eulerian tour in the graph

- corollary: as the length of any edge of Gⁱ is ¹/_{2ⁱ}, error in patching any one edge of Gⁱ is ≤ ⁴/_{2ⁱ}

< □ > < 同 > < 回 >

patching lemma: patch the path with respect to a line segment

- corollary: as the length of any edge of Gⁱ is ¹/_{2ⁱ}, error in patching any one edge of Gⁱ is ≤ ⁴/_{2ⁱ}
- corollary: viewing the portal is of zero lengthed segment, any optimal solution need to use a portal at most twice (hence, we are allowing 2 intersections per portal in the apprx tour)

(Arora's PTAS for the Euclidean TSP)

patching grid edges at every level of the quadtree

• while considering quadtree nodes in bottom-to-top⁵, at every level $H \ge i \ge 1^6$, patch the tour π_{opt} w.r.t. every grid edge of G^i :

if the current tour intersects e more than r times so that it intersects e at most twice after patching

 ${}^{6}G^{0}$ does not intersect the generated path (Arora's PTAS for the Euclidean TSP)

・ロト・「聞ト・「叫ト・「」、

⁵when we fix an edge of a grid so that the tour does not intersect it too many times, the number of times the patched tour crosses boundaries of higher-level nodes of the quadtree also goes down; similarly, the total number of crossings (of the tour with the grids) drop exponentially as we use larger and larger grids; thus requiring fewer fix-ups; thus, intuitively, one can think about all the patching happening in the bottom level of the quadtree

patching grid edges at every level of the quadtree

• while considering quadtree nodes in bottom-to-top⁵, at every level $H \ge i \ge 1^6$, patch the tour π_{opt} w.r.t. every grid edge of G^i :

if the current tour intersects e more than r times so that it intersects e at most twice after patching

let π_i denote the resulting path after patching at G^i

let π_{i+1} denote the path just before patching at G^i

 π_{H+1} is π_{opt} , and π_1 is the patched tour after patching at every level from H to 1

⁵when we fix an edge of a grid so that the tour does not intersect it too many times, the number of times the patched tour crosses boundaries of higher-level nodes of the quadtree also goes down; similarly, the total number of crossings (of the tour with the grids) drop exponentially as we use larger and larger grids; thus requiring fewer fix-ups; thus, intuitively, one can think about all the patching happening in the bottom level of the quadtree

 ${}^{6}G^{0}$ does not intersect the generated path (Arora's PTAS for the Euclidean TSP)

exploiting sliding grid

randomly choose the unit grid origin from $[0,0] \times [\frac{1}{2}, \frac{1}{2}]$:

 for every level i ≥ 1 of the quadtree, the expected number of intersections of a polyline w with the vertical and horizontal edges of Gⁱ is at most 2ⁱ⁺¹ ||w|| ← probabilistic argument is due to sliding grid

-----(1)

▲□▶▲□▶▲□▶▲□▶ = のへの

exploiting sliding grid

randomly choose the unit grid origin from $[0,0] \times [\frac{1}{2}, \frac{1}{2}]$:

- if a point *p* belongs to open edges of G^i then the point *p* belongs to open edges of G^{i-1} with probability $\frac{1}{2}$ (as every grid edge of G^i has probability $\frac{1}{2}$ to survive and be a grid edge of G^{i-1})

 F_i : number of patching operations performed at i^{th} level; Y_i : number of times the current tour crosses the edges of G^i just before considering G^i for patching; n_i : number of times the current tour crosses the edges of G^i after patching

expected increase in length of π_{opt} due to patchings at every level

$$\begin{split} &= E[\sum_{i=1}^{H} \frac{4F_i}{2^i}] \quad (\text{due to } (0)) \\ &\leq E[2F_1 + \sum_{i=2}^{H} \frac{4F_i}{2^i}] \\ &\leq E[2F_1] + \frac{4}{r-2} \sum_{i=2}^{H} \frac{E[Y_i] - 2E[Y_{i-1}]}{2^i} \\ &\quad (\text{noting that due to } (2), E[Y_{i-1}] = E[E[Y_{i-1}|n_i]] = E[\frac{n_i}{2}], \text{ and} \\ &\quad E[Y_i] = E[\frac{n_i}{2}] \leq E[\frac{Y_i - (r-2)F_i}{2}] = \frac{1}{2}E[Y_i] - \frac{k-2}{2}E[F_i]) \\ &\leq E[2\frac{Y_1}{r-2}] + \frac{4}{r-2} \left(\frac{E[Y_H]}{2^H} - \frac{E[Y_1]}{2}\right) \quad (\text{since } F_1 \leq \frac{Y_1}{r} \leq \frac{Y_1}{(r-2)}) \\ &= \frac{4}{r-2} \left(\frac{E[Y_1]}{2^H} + \frac{E[Y_H]}{2^H} - \frac{E[Y_1]}{2}\right) \\ &\leq \frac{4}{r-2} \frac{E[Y_H]}{2^H} \quad (\text{note that } Y_H \text{ is the number of times } \pi_{opt} \text{ crosses the edges of } G^H) \\ &= \frac{4}{r-2} \frac{2^{H+1}OPT}{2^H} \quad (\text{due to } (1)) \end{split}$$

(Arora's PTAS for the Euclidean TSP)

 F_i : number of patching operations performed at i^{th} level; Y_i : number of times the current tour crosses the edges of G^i just before considering G^i for patching; n_i : number of times the current tour crosses the edges of G^i after patching

expected increase in length of π_{opt} due to patchings at every level

$$\begin{split} &= E\left[\sum_{i=1}^{H} \frac{4F_i}{2^i}\right] \text{ (due to (0))} \\ &\leq E\left[2F_1 + \sum_{i=2}^{H} \frac{4F_i}{2^i}\right] \\ &\leq E\left[2F_1\right] + \frac{4}{r-2} \sum_{i=2}^{H} \frac{E[Y_i] - 2E[Y_{i-1}]}{2^i} \\ &\text{ (noting that due to (2), } E[Y_{i-1}] = E[E[Y_{i-1}|n_i]] = E[\frac{n_i}{2}], \text{ and} \\ &E[Y_i] = E[\frac{n_i}{2}] \leq E[\frac{Y_i - (r-2)F_i}{2}] = \frac{1}{2}E[Y_i] - \frac{k-2}{2}E[F_i]) \\ &\leq E\left[2\frac{Y_1}{r-2}\right] + \frac{4}{r-2} \left(\frac{E[Y_H]}{2^H} - \frac{E[Y_1]}{2}\right) \quad (\text{since } F_1 \leq \frac{Y_1}{r} \leq \frac{Y_1}{(r-2)}) \\ &= \frac{4}{r-2} \left(\frac{E[Y_H]}{2^H} - \frac{E[Y_1]}{2}\right) \\ &\leq \frac{4}{r-2} \frac{E[Y_H]}{2^H} \quad (\text{note that } Y_H \text{ is the number of times } \pi_{opt} \text{ crosses the edges of } G^H) \\ &= \frac{4}{r-2} \frac{2^{H+1}OPT}{2^H} \quad (\text{due to (1))} \\ &= \frac{8}{r-2} OPT \end{split}$$

(Arora's PTAS for the Euclidean TSP)

• as noted, after applying patching lemma to grid squares at all levels from bottom-to-top, the tour intersects with any edge of any grid square at most twice

⁷ for $i \ge 1$, tour π_i (esp. π_1) has at least as many crossings with G_i as π_{opt} has with G_i ⁸ if a grid edge has portals from several levels, the snapped tour used only the portals on this edge that belong to the highest level (Arora's PTAS for the Euclidean TSP) $\cong 21/25$

- as noted, after applying patching lemma to grid squares at all levels from bottom-to-top, the tour intersects with any edge of any grid square at most twice
- as the distance between any two successive portals along any edge of Gⁱ is ^{1/2ⁱ}/_{m+1}, a single snapping operation on an edge of Gⁱ introduces an error ≤ 2(^{1/2ⁱ}/_{2(m+1)}) = ¹/_{2ⁱ(m+1)}

- as noted, after applying patching lemma to grid squares at all levels from bottom-to-top, the tour intersects with any edge of any grid square at most twice
- as the distance between any two successive portals along any edge of Gⁱ is ^{1/2ⁱ}/_{m+1}, a single snapping operation on an edge of Gⁱ introduces an error ≤ 2(^{1/2ⁱ}/_{2(m+1)}) = ¹/_{2ⁱ(m+1)}

• let Z_i be the number of intersections of π_{opt} with G^i for $i \ge 1$ ⁷

due to (1), $E[Z_i] \le 2^{i+1}OPT$

- as noted, after applying patching lemma to grid squares at all levels from bottom-to-top, the tour intersects with any edge of any grid square at most twice
- as the distance between any two successive portals along any edge of Gⁱ is ^{1/2i}/_{m+1}, a single snapping operation on an edge of Gⁱ introduces an error ≤ 2(^{1/2i}/_{2(m+1)}) = ¹/_{2ⁱ(m+1)}
- let Z_i be the number of intersections of π_{opt} with G^i for $i \ge 1$ ⁷ due to (1), $E[Z_i] \le 2^{i+1}OPT$
- expected increase in length due to snapping π_1 to the portals of the quadtree (summed over all the levels)⁸ $\leq E[\sum_{i=1}^{H} \frac{Z_i}{2^i(m+1)}] \leq \frac{2H}{m+1}OPT$

⁷ for $i \ge 1$, tour π_i (esp. π_1) has at least as many crossings with G_i as π_{opt} has with G_i ⁸ if a grid edge has portals from several levels, the snapped tour used only the portals on this edge that belong to the highest level (Arora's PTAS for the Euclidean TSP) 21/25

overall apprx factor

• $(1 + \frac{\epsilon}{2})(1 + \frac{8}{r-2})(1 + \frac{2H}{m+1})OPT$ $\leq (1 + \frac{\epsilon}{2})(1 + \frac{\epsilon}{10})^2 OPT$ (by choosing $r = \frac{90}{\epsilon} = O(\frac{1}{\epsilon})$ and $m \geq \frac{20H}{\epsilon} = O(\frac{\lg n}{\epsilon})$) $\leq (1 + \epsilon)OPT$

overall apprx factor

•
$$(1 + \frac{\epsilon}{2})(1 + \frac{8}{r-2})(1 + \frac{2H}{m+1})OPT$$

 $\leq (1 + \frac{\epsilon}{2})(1 + \frac{\epsilon}{10})^2 OPT$ (by choosing $r = \frac{90}{\epsilon} = O(\frac{1}{\epsilon})$ and $m \geq \frac{20H}{\epsilon} = O(\frac{\lg n}{\epsilon})$)
 $\leq (1 + \epsilon)OPT$

hence, the apprx factor in expectation is $(1 + \epsilon)$ and the time complexity is $n(\frac{\lg n}{\epsilon})^{O(1/\epsilon)}$ i.e., randomized PTAS

take-home lessons

- PTAS in expectation
- rounding input points
- Steiner points (portals) along grid edges
- dynamic programming
- locally patching a path
- Hochbaum-Mass shifting grid technique
- applicable in various contexts: minimum Steiner tree, k-TSP, k-MST, Euclidean min-cost perfect matching

hence, the Godel award for the result!
